

```
@EnableZuulProxy
@SpringBootApplication
public class RegisterGatewayZuulAggregationApplication {
 public static void main(String[] args) {
   Spring Application.run (Register Gateway Zuul Aggregation Application. class,\ args);
}
 @Bean
 @LoadBalanced
 public RestTemplate restTemplate() {
   return new RestTemplate();
3.创建实体类
@Data
public class User {
 private int id;
 private String userName;
 private String passWord;
4.创建Java类, 名为AggregationService
@Service
public class AggregationService {
 @Autowired
 private RestTemplate restTemplate;
```

```
@HystrixCommand(fallbackMethod = "fallback")
 public Observable < User > getUserById(Long id) {
    // 创建一个被观察者
                                                                                             ß
                                                                                             0
    return Observable.create(observer -> {
      // 请求用户微服务的/{id}端点
                                                                                             <
      User user = restTemplate.getForObject("http://cloud-register-user/{id}", User.class, id);
                                                                                            <u>...</u>
      observer.onNext(user);
      observer.onCompleted();
    });
                                                                                             }
                                                                                             @HystrixCommand(fallbackMethod = "fallback")
 public Observable < User > getMovieUserByUserId(Long id) {
    return Observable.create(observer -> {
      // 请求未创建服务的/user/{id}端点,本cloud没有这个微服务你可以自行创建
      User otherUser = restTemplate.getForObject("http://cloud-consumer-user/user/{id}", User 📵
      observer.onNext(otherUser);
      observer.onCompleted();
    });
 }
 public User fallback(Long id) {
    User user = new User();
    user.setId(-1);
    return user;
 }
}
5.创建Controller
@RestController
public class AggregationController {
 public static final Logger LOGGER = LoggerFactory.getLogger(AggregationController.class);
 @Autowired
 private AggregationService aggregationService;
 @GetMapping("/aggregate/{id}")
 public DeferredResult<HashMap<String, User>> aggregate(@PathVariable Long id) {
    Observable < HashMap < String, User >> result = this.aggregateObservable(id);
    return this.toDeferredResult(result);
 public Observable<HashMap<String, User>> aggregateObservable(Long id) {
    // 合并两个或者多个Observables发射出的数据项,根据指定的函数变换它们
    return Observable.zip(
        this.aggregationService.getUserById(id),
        this.aggregationService.getMovieUserByUserId(id),
        (user, otherUser) -> {
           HashMap < String, User > map = Maps.newHashMap();
           map.put("user", user);
           map.put("otherUser", otherUser);
           return map;
        }
    );
 }
                                                                                            (!)
 public DeferredResult<HashMap<String, User>> toDeferredResult(Observable<HashMap<String, User>> details) {
    DeferredResult<HashMap<String, User>> result = new DeferredResult<>();
    // 订阅
```

```
details.subscribe(new Observer<HashMap<String, User>>() {
      @Override
      public void onCompleted() {
                                                                                                 凸
         LOGGER.info("完成...");
                                                                                                 <
                                                                                                 <u>...</u>
      @Override
      public void onError(Throwable throwable) {
         LOGGER.error("发生错误...", throwable);
                                                                                                 @Override
      public void onNext(HashMap<String, User> detail) {
         result.setResult(detail);
    });
    return result;
 }
}
```

这样,代码就编写完成了,不太熟悉RxJava的盆友,建议花一点时间入门RxJava。

## 6.测试

- (1)启动cloud-discovery-eureka, port=8001
- (2)启动cloud-register-user, port=8002
- (3)启动cloud-register-gateway-zuul-aggregation, port=8030
- (4)访问http://127.0.0.1:8030/aggregate/1,可获得如下结果

← → C ① localhost:8030/aggregate/1

{"user":{"id":1, "userName":"cloud", "passWord":"cloud"}, "otherUser":{"id":-1, "userName":null, "passWord":null}}

https://blog.csdn.net/Sta

由上图可知,本项目即实现了zuul聚合微服务,也实现了Hystrix容错。

## 扫我有惊喜
